Art Unit: 1793

DETAILED ACTION

The following is a quotation of the first paragraph of 35 U.S.C. 112:

The specification shall contain a written description of the invention, and of the manner and process of making and using it, in such full, clear, concise, and exact terms as to enable any person skilled in the art to which it pertains, or with which it is most nearly connected, to make and use the same and shall set forth the best mode contemplated by the inventor of carrying out his invention.

Claims 16 and 17 are rejected under 35 U.S.C. 112, first paragraph, as failing to comply with the written description requirement. The claim(s) contains subject matter which was not described in the specification in such a way as to reasonably convey to one skilled in the relevant art that the inventor(s), at the time the application was filed, had possession of the claimed invention.

Applicants are requested to point out support in the instant specification, by page and line numbers, for passing the "further purified gas stream" (i.e., gas stream from the 1st catalyst bed) to the second catalyst bed then to the third adsorption bed as required in the instant claim 16. It is noted that in the instant specification, the gas stream to be treated is passed through the second catalyst bed (bed "10" in Figure 1) and third adsorption bed ("11") before passing through the first catalyst bed (bed 12) (note page 12, line 31 to page 13, line 7), not after as required in the instant claim 16.

There is no sufficient support for passing the "further purified gas stream" (gas stream from the 1st catalyst bed) to the first adsorption bed. It is noted that in the instant specification, it is disclosed that the "first" adsorption bed is denoted as layers "3" and "4" in Figure 1 (note page 12, lines 23-26) and the "first" adsorption bed may "comprised upstream of an activated carbon containing potassium iodide to remove compounds of

Art Unit: 1793

mercury, arsenic and sulfur, followed by a second bed composed of an activated alumina or an activated carbon impregnated with caustic or with sodium carbonate to remove acids, such as ...HCN, etc." (note page 16, lines 6-15). The gas to be treated is passed through the first adsorption bed ("3" and "4" in Figure 1) before the passing through the first catalyst bed ("12"), not after as now required in the instant claim 17.

The following is a quotation of the second paragraph of 35 U.S.C. 112:

The specification shall conclude with one or more claims particularly pointing out and distinctly claiming the subject matter which the applicant regards as his invention.

Claims 13-24 are rejected under 35 U.S.C. 112, second paragraph, as being indefinite for failing to particularly point out and distinctly claim the subject matter which applicant regards as the invention.

In claim 13, the preamble states that the gas stream contains "at least one impurity selected from oxygen (O₂) and unsaturated hydrocarbons"; however, in step (b), it is required that "at least part of the oxygen *and* at least one unsaturated hydrocarbon" are converted to one more catalysis products.

The following is a quotation of 35 U.S.C. 103(a) which forms the basis for all obviousness rejections set forth in this Office action:

(a) A patent may not be obtained though the invention is not identically disclosed or described as set forth in section 102 of this title, if the differences between the subject matter sought to be patented and the prior art are such that the subject matter as a whole would have been obvious at the time the invention was made to a person having ordinary skill in the art to which said subject matter pertains. Patentability shall not be negatived by the manner in which the invention was made.

Art Unit: 1793

Claims 13-15, 17-18, 20-22, 24 are rejected under 35 U.S.C. 103(a) as being unpatentable over Carr (5,451,384) in view of Pham et al (6,548,440) and Krueger (4,034,062).

Carr '384 discloses a process for substantially removing the metal carbonyl content of a gas stream comprised at least 5 mol% of carbon monoxide, the process comprising contacting the gas stream with lead oxide dispersed on a support under conditions such that the metal carbonyl in the gas is removed (note column 3, lines 20-24). The metal carbonyl can be iron carbonyl, nickel carbonyl (note claims 2-3).

The gas stream to be treated can be synthesis gas for use in processes such as ammonia synthesis, methanol synthesis, Fischer-Tropsch synthesis (note column 3, lines 56-62). The synthesis gas comprises 10-90% by volume carbon monoxide, about 10-about 90% by volume hydrogen, and 0 to 80% by volume of nitrogen, the balance being made up of other gaseous components such as carbon dioxide, methane, higher hydrocarbons and oxygenated hydrocarbons, hydrogen sulphide, water, argon and traces of noble gases (note paragraph bridging column 3-4).

Carr '384 teaches that the advantages of using a PbO on gamma alumina sorbent are many. The removal is fast. It may involve a chemical reaction and/or a strong physical adsorption. The loading of Fe deposited from Fe(CO)₅ removal can be very high. These factors are conducive to commercially attractive performance: a high capacity for Fe capture, the long life of the sorbent and the ability to use small removal reactors because of fast rates of removal (note column 3, lines 38-46). The lead oxide is termed as "sorbent" in the invention of Carr '384 (note column 4, lines 42-43). Thus.

Art Unit: 1793

the lead oxide dispersed on a support as disclosed in Carr '384 is considered the same as the claimed "second adsorption bed".

The gas hourly space velocity of about 1000 GVHSV is used (note Example2). This value overlaps the claimed range at 1000. In any event, it would have been obvious to one skill in the art to optimize the gas hourly space velocity to effectively remove the metal carbonyl with the fastest possible rate.

For claim 17, Carr '384 discloses that the sulphur compounds, such as H_2S , will poison the catalysts used in processes downstream of the metal carbonyl trap. It is also known that certain sulphur compounds will compete with the removal of metal carbonyls from the gas stream. Accordingly, the gas stream is preferable free from sulfur compounds. Various sulfur compounds may be removed from the gas stream by any of the methods well known in the art. Such methods include, for example the use of zinc oxide for H_2S removal (note column 4, lines 11-20). The zinc oxide is considered as the first adsorption bed. For the order to removing the sulfur compound, it would have been obvious to one skilled in the art to remove the sulfur compounds in any order as long as they are removed before the gas stream comes into contact any catalyst.

The difference is Carr '384 does not disclose the step of treating the gas stream, after removing metal carbonyl impurity, to remove oxygen and hydrocarbon.

Pham '440 discloses that in a Fischer-Tropsch process, it is preferred in the art to purify the syngas used as the starting material (i.e. a gas stream comprising hydrogen

Art Unit: 1793

and carbon monoxide) to remove oxygen, iron carbonyls, water and hydrocarbon impurities (note column 16, lines 40-45).

Krueger '062 discloses a process for the purification of a gas stream containing primarily hydrogen and carbon monoxide as well as small quantities of oxygen, acetylene and ethylene as impurities, comprising passing said gas stream at a temperature of 250 to 700°F (121-371°C) through a bed of catalyst consisting essentially of a copper catalyst (note claim 1).

Krueger '062 further teaches that hydrogenation processes for removing oxygen, acetylene and ethylene are well known and no departures from well-known hydrogenation processes are required herein. The pressure is in the range of 100 to 500 psig (6.9 to 34.5 bar) (note column 1, lines 65-67). The space velocity is in the range of 2,000 to 10,000 gas volumes per volume of catalyst per hour, depending on the type of catalyst used (note column 1, line 67 to column 2, line 2). These ranges overlap the claimed ranges. With respect to the encompassing and overlapping ranges previously discussed, the subject matter as a whole would have been obvious to one of ordinary skill in the art at the time of invention to select the portion of the prior art's range which is within the range of the applicants' claims because it has been held prima facie case of obviousness to select a value in a known range by optimization for the results. In re Boesch, 205 USPQ 215. Additionally, the subject matter as a whole would have been obvious to one of ordinary skill in the art at the time invention was made to have selected the overlapping portion of the range disclosed by the reference because

Art Unit: 1793

overlapping ranges have been held to be a prima facie case of obviousness. In re Malagari, 182 USPQ 549.

The step of contacting the synthesis gas with the copper catalyst as disclosed in Krueger '989 would inherently remove any NO_x compounds that may be present in the synthesis gas.

It would have been obvious to one of ordinary skill in the art at the time the invention was made to remove oxygen and hydrocarbon contained in the synthesis gas of Carr '384 by the method as suggested by Krueger '989 because Pham '440 teaches that these impurities need to be removed before the syngas is used in a Fischer-Tropsch process.

Claims 16 is rejected under 35 U.S.C. 103(a) as being unpatentable over Carr '384 in view of Pham '440 and Krueger '062 as applied to claims 13-15, 17-18, 20-22, 24 above, and further in view of Heyd (4,740,361) and Britton et al (4,175,928).

The difference not yet discussed is Carr '384 does not disclose the step of removing organosulfur compound.

Heyd '361 teaches that syngas commonly contains organosulfur compound, such as methyl mercaptan as impurity in addition to inorganic sulfur compound, such as hydrogen sulfide.

Britton '928 discloses that it is known in the art to remove sulfur compounds, organic sulfur compounds from synthesis gas by first converting them to hydrogen sulfide in a catalytic hydrogenation reactor and the hydrogen sulfide is then adsorbed

Art Unit: 1793

from the synthesis gas stream by passing it through a suitable sorbent (note column 1, lines 64-68).

It would have been obvious to one of ordinary skill in the art at the time the invention was made to remove organosulfur compound, which is commonly contained in syngas, as suggested by Heyd '361, from the syngas in the process of Carr '384 by using the method of Britton '928 to improve the purity of the syngas.

Claims 18-19, 23 are rejected under 35 U.S.C. 103(a) as being unpatentable over Carr '384 in view of Pham '440 and Krueger '062 as applied to claims 13-15, 17-18, 20-22, 24 above, and further in view of Bancon et al (2003/0126989) and Engelbrecht et al (4,320,100).

The difference not yet discussed is Carr '384 does not disclose the presence of NO_x and the step of removing it.

As stated above, the step of removing oxygen and hydrocarbon as suggested by Krueger '062 would inherently remove any NOx present in the syngas.

In any event, Bancon '989 is applied to teach that synthesis gas may contain other impurities such as light hydrocarbon impurities, CO_2 and/or NO_x (note paragraphs [0020] and [0030]).

Engelbrecht '100 is applied to teach that it is conventional in the art to remove nitrogen oxide and oxygen from a synthesis gas by passing the gas over a hydrogenation catalyst at a temperature of from 120 to 250°C and at a pressure of from 0.5 to 250 bar (note claim 1).

It would have been obvious to one of ordinary skill in the art at the time the invention was made to remove nitrogen oxide, which is a common impurity in synthesis gas as suggested by Bancon '989, from the synthesis gas of Carr '384 by the method as suggested by Engelbrecht '100 because Engelbrecht '100 teaches that the desire to remove the nitrogen oxide impurity from synthesis gas.

Bancon '989 can be further applied to teach that If the amount of CO_2 contained in the stream of syngas to be purified is greater than several thousands of ppm, it is firstly washed with amines (MEA or MDEA type) to remove most of the CO_2 . The gas is then sent to a column of adsorbent(s) to remove the residual traces of CO_2 (a few tens of ppm) not removed by the washing with amines and possibly the other impurity or impurities present in the syngas, for example water that is often present at the same time as CO_2 (after washing with the amines, the gas is saturated with water) (note paragraph [0007]).

Applicant's arguments with respect to claims 13-24 have been considered but are moot in view of the new ground(s) of rejection.

The prior art made of record and not relied upon is considered pertinent to applicant's disclosure.

Art Unit: 1793

Any inquiry concerning this communication or earlier communications from the examiner should be directed to Ngoc-Yen M. Nguyen whose telephone number is (571) 272-1356. The examiner can normally be reached on Part time schedule.

If attempts to reach the examiner by telephone are unsuccessful, the examiner's supervisor, Stanley Silverman can be reached on (571) 272-1358. The fax phone number for the organization where this application or proceeding is assigned is 571-273-8300.
